### ABSTRACT

Zinc oxide nanoparticles (NPs) have emerged as a novel elicitor for enhanced biosynthesis of secondary metabolites in *in vitro* plant cell cultures. The current study was aimed to explore elicitation abilities of ZnO-NPs for enhanced accumulation of lignans and neolignans in cell cultures of *Linum usitatissimum*. We optimized concentration of zinc oxide NPs before carrying out a full-fledged experiment. Subsequently, an optimum dose of 100 mg/l was introduced into the culture medium on day 0, days 0 and 15, and finally days 0 and 25. We observed that repeated elicitation stimulated various parameters and physiological responses in *Linum usitatissimum* cell cultures than one-time elicitation. Repeated elicitation of cell cultures on day 0 and 15 resulted in highest fresh weight (412.16 g/l) and lignans production (secoisolariciresinol diglucoside 284.12 mg/l; lariciresinol diglucoside 86.97 mg/l). Contrarily, repeated elicitation on day 0 and 25 resulted in highest DW (13.53 g/l), total phenolic production (537.44 mg/l), total flavonoid production (123.83 mg/l) and neolignans production (dehydrodiconiferyl alcohol glucoside 493.28 mg/l; guaiacylglycerol- $\beta$ -coniferyl alcohol ether glucoside 307.69 mg/l). Enhancement in plant growth and secondary metabolites accumulation was several fold higher than controls. Furthermore, a linear relationship existed between total phenolic and flavonoid contents which in turn was correlated with higher antioxidant activities.

## Introduction

*Linum usitatissimum*, a novel plant belonging to the family linaceae has a rich history regarding industrial applications—linen fiber production and linseed oil extraction—however, currently it is increasingly exploited as a great source of some health-promoting phenolic metabolites known as lignans and neolignans [1]. These metabolites are naturally occurring polyphenols, which have potential therapeutic applications mainly against different types of cancer, some microbial infections and inflammation as well. Major lignans are secoisolariciresinol diglucoside (SDG) and lariciresinol diglucoside (LDG), whereas dehydrodiconiferyl alcohol glucoside (DCG) and guaiacylglycerol- $\beta$ -coniferyl alcohol ether glucoside (GGCG) are well-known neolignans [2]. Both lignans and neolignans share similar structural conformation, but they can be easily characterized by difference in (a minor but significant) bonding pattern. Generally, lignans consist of phenylpropane dimers that are bonded through the carbon atoms (C8/C8~) of their side chains, whereas in neolignans,

these dimers are connected through bond other than C8/C8~ [3].

A variety of established techniques and methods exist for commercial production of phytomedicines. Among these, biotechnology-based plant cell cultures are superior and modern methods, employed for extraction and isolation of phytomedicinal products. However, certain modifications and adaptations to such a system on the whole or some operational conditions are essential for enhanced accumulation of plant-derived secondary metabolites because production potential of such systems is intrinsically low, therefore they need stimulation [4]. For this purpose, elements of diverse nature are used as stimulatory agents, which elicit enhanced biosynthesis of secondary metabolites in *in vitro* plant cell cultures. These agents include elements from both biotic and abiotic sources [5]. Nanoparticles (NPs) are emerging abiotic elicitors used for obtaining improved yields of plant-derived medicinal compounds, such as, recently, we have reported effective scheme for elicitation of *Linum usitatissimum* derived cell suspension cultures through addition of

chemogenic Ag-NPs [6]. Generally, NPs have distinct physico-chemical properties that enable them to interact with plant metabolic systems in a conducive way, rarely observed while using source/candidate material in raw form [7,8]. Furthermore, zinc as a micronutrient play a significant role in plant growth and metabolism. Phyto-hormonal regulation especially auxins, carbohydrate metabolism, protein synthesis [9] and stress alleviating responses have been associated with adequate supply of zinc [10,11]. In addition, a great number of reports have described positive aspects of ZnO-NPs regarding their impacts on plant growth, physiology and secondary metabolism, details of which are provided in the discussion section. Thus, the current study was also aimed along the same lines to enhance accumulation of poly-phenolic secondary metabolites (lignans and neolignans) in cell suspension cultures of *Linum usitatissimum* using biogenic ZnO-NPs as an abiotic elicitor.

## Materials and methods

### Inoculum preparation

The inoculum was prepared according to our previous protocol [6]. Both callus and cell suspension cultures were grown on MS medium as described previously [2]. Firstly, aseptically excised stem explants from *Linum usitatissimum*'s seed germinated plantlets were inoculated on MS medium containing 1 mg/l NAA as a PGR and agar as a solidifying agent, for callus induction (Figure 1(A)). Secondly, callus obtained was immersed in liquid MS medium comprising same chemical constituents to that of callus inducing medium, but without agar (Figure 1(B)). These cultures were maintained in controlled conditions on a shaker for 15 days and then used for establishment of cell suspension cultures.

### Characteristics of ZnO-NPs

ZnO-NPs were biologically synthesized using root extracts of *Linum usitatissimum* and described by our research group earlier [12]. Adventitious roots extract of *Linum usitatissimum* (10 g/100 ml) and zinc nitrate hexahydrate (0.1 mM) were mixed in same proportions and then heated at 60 °C for 3 h under continuous stirring. Synthesis of ZnO-NPs was detected by precipitation of yellow particulates and later validated by UV-visible spectroscopy. Particles size, shape and texture

were analyzed using XRD and TEM techniques, respectively. XRD results confirmed that NPs were hexagonal in shape with crystalline appearance, whereas the average size was up to 35 nm as examined by TEM. The physical stability of ZnO-NPs was determined using UV-visible spectroscopy before its application. For this purpose, absorbance value of 2.5 and peak value between 230 and 800 nm were used as standard parameters.

### Optimization of ZnO-NPs concentration

Current experiment spanned for a total of 40 days. At first, an optimum dose of ZnO-NPs was determined for elicitation of cell suspension cultures. Consequently, a dose of biogenic ZnO-NPs, i.e. 1, 5, 10, 20, 30, 40, 50, 75, 100, 200 and 500 µg/l, respectively, was introduced to cell suspension cultures on day zero. All experimental elicitation steps were carried out in liquid MS medium containing 10 ml inoculum.

### ZnO-NPs treatments

During the optimization experimental part, we recorded that 100 µg/l ZnO-NPs resulted in maximum fresh and dry biomass accumulation on day 25 after the initial day of culturing, therefore, we carried on this dose of ZnO-NPs for further experimentation. ZnO-NPs were introduced periodically into cell suspension cultures on three occasions, firstly on day 0, secondly on day 0 and 15, and finally day 0 and 25 (Figure 1(C)). Cells from culture medium were harvested at periodical breaks of 5 days until day 40 of the cell suspension culture, after each elicitation step. Control treatment did not receive any dose of ZnO-NPs at any stage.

### Biomass determination

Cells harvested from culture medium were gently squeezed using several layers of filter papers to extract excess water. Fresh weight was recorded instantly; using electronic weighing balance, afterward cells were dried at 50 °C in a heating incubator until 24 h, and then dry weight was recorded. Both fresh and dry biomass were expressed in g/l.

**Figure 1.** A: *In vitro* established callus culture of *Linum usitatissimum*. B: Inoculum for cell suspension cultures of *Linum usitatissimum*, derived from *in vitro* established callus culture. C: Cell suspension cultures of *Linum usitatissimum* fed at day 0, day 0 and 15 and day 0 and 25, respectively.

### Phytochemical analysis

Methanolic extracts of dried and powdered cells were used for phytochemical analysis; 50 mg samples were suspended in 250  $\mu$ l methanol, then vortexed for 3 min and sonicated for 30 min, respectively. Next, samples were subjected to centrifugation at 13,000 rpm for 5 min. The supernatant obtained was collected carefully and kept for phytochemical analysis. Total flavonoid content (TFC) was evaluated using aluminium chloride colorimetric method as described by Ul-Haq et al. [13]. Total flavonoid production (TFP) was mathematically calculated according to the method of Zahir et al. [2] and expressed as mg/l. Total phenolic content (TPC) was evaluated using the Folin-Ciocalteu (FC) method as reported by Singleton et al. [14]. Total phenolic production (TPP) was also mathematically calculated according to the method described earlier [2] and expressed as mg/l.

### Free radical scavenging assay

1,1-Diphenyl-2-picrylhydrazyl (DPPH) was used as a source of free radicals to assess the scavenging capacity of samples collected from cell suspension cultures, according to the method of [15]. Methanol based cellular extracts and DPPH solution were mixed and kept in dark for 30 min. FRSA was evaluated using spectrophotometer at 517 nm and calculations based on the comparison of absorbance values was used to obtain % FRSA of samples [2].

### HPLC analysis

Accumulation of polyphenols (lignans and neolignans) in cell suspension cultures was quantified using HPLC following method of Corbin et al. [16]. Production of polyphenols was calculated from HPLC data as follows:

$$\text{Production (lignans or neolignans) mg/l} \\ = \text{Content (lignans or neolignans) mg/g} \times \text{Dry weight g/l}$$

### Statistical analysis

Experimental design was based on triplicates, repeated twice and were conducted in controlled conditions. ANOVA test was applied to experimental data using Origin Pro software (8.5). All values are presented as means  $\pm$  SD. Origin Pro 8.5 was used for the generation of all graphs.

### Results and discussion

Physiological responses are the first key changes, which occur when plants are exposed to elements of diverse nature. NPs trigger plant physiological response in both positive and negative ways [17,18], primarily depending on the concentration of NPs and plant species [19,20]. Generally, application of NPs in lower concentrations has been found promoting plant growth and secondary metabolites production [21]. We observed the positive impacts of ZnO-NPs on biomass accumulation in *Linum usitatissimum* derived cell suspension

**Figure 2.** Temporal effects of repeated elicitation with biogenic ZnO-NPs on fresh biomass of cell suspension cultures of *Linum usitatissimum*. Values are mean of triplicates  $\pm$  SD.

cultures, as we obtained maximum fresh weight, 412.16 g/l—on day 35 after initial culturing when cell suspension cultures were repeatedly elicited on day 0 and 15—(Figure 2) and dry weight, 13.53 g/l—on day 30 after initial culturing when cell suspension cultures were repeatedly elicited on day 0 and 25—(Figure 3), respectively. Our observations are in accordance with the current perspective on using ZnO-NPs as a potential nanofertilizer, which is gaining wide acceptance because of the increasing reports on their positive impacts on plant growth [22,23]. These reports described the growth promoting effects of ZnO-NPs as a result of effective physiological changes including regulation of plant pigments directly associated with biomass buildup such as chlorophyll and carotenoids [24,25]; increase in nutrients uptake efficiency [26], upregulation of antioxidant metabolism [27] and

most important, the involvement of zinc as an essential micronutrient in the metabolism of different plant biomolecules [28].

Accumulation of phenolics and flavonoids in response to novel substances as a primary defense line is the principal indicator of active plant secondary metabolism Zahir et al. [29]). *Linum usitatissimum* contains a wide range of phenolics and some flavonoids. In the current study, similar trends were observed for both phenolics and flavonoids accumulation, we noted that one-time elicitation had not impacted phenolic and flavonoid contents but repeated addition of ZnO-NPs into culture medium, especially at a later stage of culture—log phase—significantly enhanced both total phenolic and flavonoid content/production, respectively, as

compared to control treatments. Optimum TPC (39.71 mg GAE/g) and TPP (537.44 mg/l) occurred on day 30 after initial culturing when cell suspension cultures were repeatedly elicited on day 0 and 25 (Figures 4 and 5). This increase in phenolics production was 15.8 fold as compared to control. Optimum TFC and TFP also occurred during the same period. Highest TFC and TFP were recorded to be 9.15 mg QUE/g and 123.83 mg/l, (Figures 6 and 7), respectively. This increase in flavonoids production was 8.8 fold as compared to control. These results are in agreement with our previous finding [6], wherein similar trends in total phenolic and flavonoid contents were observed. Increased polyphenol accumulation is indicated by higher antioxidant activities [30]. A positive correlation between FRSA and phenolic content was recorded in the current study. Maximum FRS activity observed was up to

**Figure 8.** Temporal effects of repeated elicitation with biogenic ZnO-NPs on free radical scavenging assay of cell suspension cultures of *Linum usitatissimum*. Values are mean of triplicates  $\pm$  SD.

90% in repeatedly elicited cultures (Figure 8). Generally, repeated elicitation resulted in enhanced FRS activity at the last stages of culture as compared to control. Our results are supported by the findings of García-López et al. [31] and Zafar et al. [32] who successfully enhanced phenolics and flavonoids, and also observed maximum antioxidant activities as a result of applying ZnO-NPs during germination of *Capsicum annum* and stem explants response of *Brassica nigra*, respectively. Significant changes in all the growth parameters as compared to control were reported in these studies.

Elicitation of cell suspension cultures of *Linum usitatissimum* with ZnO-NPs also enhanced accumulation of the secondary metabolic compounds lignans and neolignans. This accumulation correlated with the TPC, as both lignans and neolignans are also polyphenols by nature. We obtained the highest lignans content/production (SDG 25.01 mg/g and 284.12 mg/l; LDG 7.65 mg/g and 86.97 mg/l) after 25 days of initial culturing when cell suspension cultures were repeatedly treated with ZnO-NPs on day 0 and 15; whereas highest neolignans content/production (DCG 36.44 mg/g and 493.28 mg/l; GCGG 22.73 mg/g and 307.69 mg/l) occurred after 30 days of initial culturing when cell suspension cultures were repeatedly treated with ZnO-NPs on day 0 and 25 (Tables 1 and 2). The mechanism underlying enhanced production of secondary metabolites in response to ZnO-NPs is still unclear, but a number of reports are available on their role as a potential abiotic elicitor during *in vitro* cultures such as Sharafi et al. [33], Karimi et al. [21] and Javed et al. [34]. Bhardwaj et al. [35] made an attempt to decipher the transcriptional regulation of ZnO-NPs induced enhanced accumulation of bacoside A content in cell suspension cultures of *Bacopa monnieri*. They suggested that reduced transcriptional levels of HMG-CoA reductase gene in response to ZnO-NPs might be a result of diverging biosynthetic pathway from mevalonate to isoprenoid pathway. Furthermore, Mosavat et al. [36] have recently reported elicitation of thymol in

callus cultures of *Thymus kotschyanus* and carvacrol in callus cultures of *Thymus daenesis* under ZnO-NPs stress.

## Conclusion

Biotechnological approach towards enhanced production of commercially important secondary metabolites from a wide range of medicinal plants is so far the best methodology as it offers flexibility in terms of manipulating growing/operational conditions and reproducibility [37]. Application of ZnO-NPs in *Linum usitatissimum* derived cell suspension cultures proved a simple but effective procedure to enhance biomass and most important, accumulation of polyphenols—lignans and neolignans—over a short period of time, possibly as a result of ZnO-NPs induced metabolic shuffling. Results obtained during this study support the positive role of ZnO-NPs as an elicitor during *in vitro* established cultures of a variety of medicinal plants.
